FIRST RECORD OF BULLOCK'S ORIOLE FOR HARFORD COUNTY, MARYLAND

DENNIS L. KIRKWOOD

2659 Bradenbaugh Road, White Hall, Maryland 21161
newarkfarms@gmail.com

The winter of 2012-13 proved to be an exciting one for birders in Maryland and throughout the mid-Atlantic region as an invasion of northern irruptive species occurred. Red-breasted Nuthatch (*Sitta canadensis*), Pine Siskin (*Spinus pinus*), Evening Grosbeak (*Coccothraustes vespertinus*), Purple Finch (*Haemorhous purpureus*), and both Red and White-winged Crossbill (*Loxia curvirostra* and *L. leucoptera*, respectively) flocks made everyone pay more attention to their backyard feeders.

On Monday, 11 February 2013 at approximately 11:00 a.m. EST, I noticed a yellow and black bird at my platform feeder on Bradenbaugh Road in northwestern Harford County. Given the irruptive season we were experiencing, my first thought was Evening Grosbeak as the bird was bigger than the finches and sparrows that typically frequented the feeder. Even though I did not have binoculars handy, I was able to get closer to the feeder and quickly revised my identification to some type of oriole. I noticed the black bib on the bird and then it flew away.

Figure 1. Immature male Bullock's Oriole (*Icterus bullockii*). Harford County, Maryland, 20 February 2013. Photographed by Jean Kirkwood.

Quickly consulting three field guides and getting my binoculars and camera ready, I waited for the bird to return, which it did in about 15 minutes. After taking a few poor quality pictures, I decided to study the bird with binoculars, this time indoors through a window while about 9 m away from the feeder. The bird showed two large wing-bars intersected by black "teeth," the black bib, and a whitish color to the belly. It also showed a distinct black spot at the base of the lower mandible. I concluded that the bird was a first-year male Bullock's Oriole (*Icterus bullockii*) (Figure 1).

(continued)

Wanting further verification, I called Matt Hafner who was able to have his wife, Dr. Kim Hafner, come over to obtain some clearer pictures and email them to him. Matt was able to verify the identification and shared the pictures with several others who also reached the same conclusion. Fortunately the bird visited for the rest of the afternoon and about 15 people were able to come and observe and photograph the bird.

Our feeder set-up consists of one 30.5-cm² platform feeder with both white millet and black-oil sunflower seeds; one hanging suet feeder; one hanging nyger seed tube; and one hanging sunflower seed tube. The feeders are outside the sliding doors of our living room in an alcove that shelters them from our driveway. A multi-trunk white birch (*Betula* sp.) and two small rhododendrons (*Rhododendron* sp.) are surrounded by eastern white pines (*Pinus strobus*) (height = 18 m) and a privet (*Ligustrum* sp.) hedge (height = 3 m). The oriole was most consistently using the platform feeder, eating the millet and avoiding the sunflower seeds, and increasingly favoring the suet feeder. One attempt to provide orange slices was ignored by the oriole.

My wife, Jean Kirkwood, realized that she had briefly seen the oriole on Sunday, 10 February 2013, one day before my discovery, and our last sighting was on Sunday, 17 March 2013. The bird would appear most days in the morning from 7:30 a.m. and feed for 5-10 minutes before flying off. Its frequency of feeding varied greatly from day to day, sometimes at 30-minutes intervals, and at other times, one visit for the entire day. This raised the question of where it was spending the rest of its time.

This mystery was solved when a neighbor, Loretta McGraw, who lived 1 km away, stopped by with pictures of the Bullock's Oriole at her feeder. She had dated photographs from 8 January through 26 April 2013. She reported that the bird used many feeders on different sides of her house and would also disappear into the shrubbery, apparently feeding on the mulched ground. She also has a large grove of white pine along the edge of her yard that the bird seemed to frequent.

According to Phil Davis (Secretary) and Matt Hafner (Member) of the Maryland/District of Columbia Records Committee (MD/DCRC), this is the third documented sighting of Bullock's Oriole for the state and the first for Harford County. This was the first time pictures were taken documenting the species in Maryland and the first time at a feeder where birders could have a reasonable chance of seeing the bird. Over the course of the 36 days it visited my feeder, approximately 175 people came to see the bird and the vast majority was successful. The two other accepted records were an adult in female-type plumage on 25 September 1994 at Blackwater National Wildlife Refuge (Dorchester County) and a male in basic plumage on 24 November 2009 at Sycamore Landing, Chesapeake & Ohio Canal National Historic Park (Montgomery County). Three other sightings were not accepted by the MD/DCRC and three additional sightings are in the review process (MD/DCRC 2013).

In addition to this Maryland bird (Adams et al. 2013), the winter of 2012-13 also recorded the species in Massachusetts (Hunt 2013), Connecticut (Hunt 2013), Pennsylvania (Fazio and Johnson 2013), North Carolina (Blankenship et al. 2013), Georgia (GCRC 2013), and Florida (Anderson 2013). The North Carolina bird was a reoccurring observation for the second year (Blankenship et al. 2013), and the Pennsylvania bird was for the third straight year (Fazio and Johnson 2013).

Addendum: In late fall 2013, a mature male Bullock's Oriole (Figure 2) was noted at my feeder on 8 December. It was presumed to be the same bird that spent the late winter in 2013. The neighbor who shared it during the 2013 winter first observed the mature male on 26 November 2013. It was very sporadic in its appearances during this time and was last seen on 5 February 2014 by Loretta McGraw at her house.

ABSTRACT

Numerous studies report American Goldfinches (*Spinus tristis*) in the mid-Atlantic Coastal Plain initiate nesting in June with maturation of regional Asteraceae thistles, and use spider and caterpillar web threads to bind various nest materials. We observed a female goldfinch gathering web from Eastern Tent Caterpillar Moth (*Malacosoma americanum*) larvae on 21 April 2012. Non-native, earlier-blooming thistle, warming climate, and availability of nyjer seed in popular backyard feeders may be factors contributing to earlier goldfinch nesting activity.

Keywords: climate warming, goldfinch, nyjer seed, thistles, web gathering

Authors generally attribute the annual start of nesting activity by the American Goldfinch (*Spinus tristis*) to coincide with maturation of Asteraceae thistles from which they use pappus (silky/feathery filaments of the modified calyx) as an important nest material and the seeds provide nestling food (Stokes 1950, Holcomb 1969, Lynch 1970, McGraw and Middleton 2009). Radford et al. (1968), and Brown and Brown (1984) indicate nearly all frequently occurring thistle species (*Cirsium* and *Centaurea* spp.) on the Coastal Plain do not bloom before late June, thus commencement of goldfinch nesting would be delayed until that time or when the first pappus appeared a few weeks later.

Mid-Atlantic Breeding Bird Atlases and regional bird books referencing Pennsylvania through North Carolina report a few American Goldfinches might initiate nest building earlier than mid-June, but nearly all first reported incidences occur in early July with maturity of thistles (Stewart and Robbins 1958, Potter et al. 1980, Santner 1992, Hess et al. 2000, Walsh et al. 1999, Rottenborn and Brinkley 2007, Ellison 2010).

Ellison (2010) noted an 8.7% shift toward June initiation of goldfinch nests during the 2002-2006 Maryland Breeding Bird Atlas. Possibly introduction and/or spread of non-native, earlier-blooming thistle species, recent years of warming and/or drier climate, and popularity of backyard feeders offering nyjer seed may all contribute to earlier nest activity.

In the Maryland Coastal Plain, on the unusually early date of 21 April 2012, K. Harris, W. Harris, and Poet observed and photographed an American Goldfinch collecting nest material at Adkins Arboretum near the town of Ridgely, Caroline County, Maryland. Presented here are our observations and comments related to this early occurrence.

METHODS

These three recreational bird observers made the goldfinch sighting while walking along designated trails at the Adkins Arboretum at about 8:50 a.m. with clear sky, 22°C and no discernible wind. We first spotted a male and female American Goldfinch perched near the top of a small black cherry (*Prunus serotina*) infested in one of the uppermost forks with webbing from Eastern Tent Caterpillar Moth (*Malacosoma americanum*) larvae. The yellow and black-winged male was positioned about 0.5 m above the drab female perched directly adjacent to the widest portion of the tent webbing about 6 m high in the tree. Poet later photographed the goldfinch activity with a hand-held, Nikon D5100 Digital SLR Camera in an Auto mode, zoomed to 300 mm magnification.

RESULTS

We first assumed the goldfinches were consuming the Eastern Tent Caterpillar Moth larvae whose webbing densely infested the tree; however upon closer inspection we ascertained the female goldfinch was collecting strands of tent webbing into and around her bill while the male watched. Figure 1 shows the female with the gathered strands of webbing within and on the bill. We watched this collecting behavior for 5-8 minutes before both birds took flight and departed our viewing area.

DISCUSSION

Many authors (Bent and Collaborators 1968, Baicich and Harrison 1997, McGraw and Middleton 2009) have cited goldfinch use of spider and caterpillar web threads for binding lichens, bark, grasses and other nest materials together, thus this behavior is not unusual. However, the date of nest material gathering is unusual since it comes nearly 60 days earlier than documented historical goldfinch nest building on the Mid-Atlantic Coastal Plain and 19 days before single May occurrences in New York City (Künstler 1994) and Maryland (Ellison

2010). Non-native, earlier-blooming thistle, warming climate, and nyjer seed available at backyard feeders (Ellison 2010) may be factors contributing to unusually early goldfinch nesting activity.

The most frequently occurring species of common and star thistles in the region of our observation are Canada, bull, and field thistle (*Cirsium arvense*, *C. vulgare*, *C. discolor*), and garden cornflower

Figure 1. Female American Goldfinch (*Spinus tristis*) collecting webbing from an Eastern Tent Caterpillar Moth (*Malacosoma americanum*) tent. Adkins Arboretum, near Ridgely, Caroline County, Maryland, 21 April 2012. Photographed by Daniel E. Poet.

(continued)

and spotted knapweed (*Centaurea cyanus*, *C. stoebe*) (Phillips 1978, Brown and Brown 1984, Kaufman and Kaufman 2007, pers. observations). These sources indicate initial flowering in July or August for native field thistle, June or August for naturalized bull thistle, June for introduced Canada thistle and spotted knapweed, and May for introduced garden cornflower. This suggests that over the past several decades, as the earlier blooming naturalized and introduced thistles have increased their numbers and range, the availability of pappus and thistle seeds may have also enabled earlier initiation of goldfinch nesting activities than during historical periods. Earlier blooming may be further enhanced by annually warming climate (Wolkovich et al. 2012) such as experienced in 2012. During the 81 days prior (1 February) to our observation the ambient temperatures ranged above the USDA-NRCS (2002) historical monthly highs on 53% of the days; there was 11.9 cm of precipitation compared with the 22.6 cm average in 1961–1985; there was no measurable precipitation 36 days prior to the event; and numerous species of local plants appeared to bloom weeks earlier than usual. The tiny, linear shape of nyjer has the appearance of thistle seed while being of greater nutritional content, thus is a strong attractant for goldfinches. Advent and marketing of the vertical, clear plastic, tube-feeder designed specifically to attract goldfinches to its nyjer content has made the seed a multi-million dollar commodity in recent years (Wild Bird Feeding Industry 2012) while tube-feeder marketing has targeted the summer-season when the finches have a bright yellow plumage. Abundant availability of nyjer all months of the year, particularly during the warm months, may also contribute to earlier goldfinch nesting activity.

Unusually early nesting activity by the American Goldfinch warrants future attention to timing of nest material gathering, nest building, egg-laying, and reproductive success in view of abundant introduced thistles, warming climate, and availability of nyjer seed.

ACKNOWLEDGMENTS

Walter G. Ellison graciously provided comments and helpful suggestions on earlier drafts.

ABSTRACT

We conducted annual aerial surveys (1991-2011) for breeding Bald Eagles (*Haliaeetus leucocephalus*) within Aberdeen Proving Ground (APG), a 350-km² military installation located along the northwestern shoreline of the upper Chesapeake Bay in Maryland. The population increased exponentially from 1 pair in 1977 to 58 pairs in 2011 with an average doubling time of 5.8 years. This rate was higher than that documented for the broader Chesapeake Bay and is comparable to the highest reported throughout the species range. Annual population increase was highly variable and exhibited no indication of any systematic decline. A total of 646 chicks were produced from 464 breeding attempts during this period. The population has exhibited tremendous forward momentum such that more than 50% of young produced over the 21-year period were produced in the last 6 years. Average success rate was high (79.8%) and reproductive rates exceeded conservation targets in nearly all years. Due to the expansion of urban development throughout the Chesapeake Bay watershed, APG plays an increasingly important role in the recovery and maintenance of the Chesapeake Bay Bald Eagle population.

Keywords: Bald Eagle, *Haliaeetus leucocephalus*, breeding, Aberdeen Proving Ground, recovery, Department of Defense

Bald Eagles (*Haliaeetus leucocephalus*) have likely bred on the land currently occupied by Aberdeen Proving Ground (APG) for thousands of years. However, no assessment of the population is available prior to the 1930s when the National Audubon Society commissioned a survey of a portion of the Chesapeake Bay that included APG (Tyrrell 1936). In 1936, Tyrrell documented nests on Eagle Point, Robbins Point, lower Little Romney Creek (north of Elm Tree Point), upper Little Romney Creek (near intersection with A-A5 road), and Bear Point. Stewart and Robbins (1958) documented nests on APG in the 1950s. Abbott (unpublished field notes) coordinated Bald Eagle nest surveys from the late 1950s through the mid-1970s and documented additional nests at the mouth of Canal Creek, Reardon Inlet (near Westwood Range), Maxwell Point, Swaderick Creek, Leges Point (near Days Point), north

of Ricketts Point, Gum Point, Skippers Point (on Lauderick Creek), Coopers Creek, Back Creek (near AA-5 road), and three on Spesutie Island (near Locust Point; near Morgan Road; near Sandy Point). Only four of these historic breeding sites had evidence of Bald Eagle use when investigated during the early 1960s (Abbott, unpublished data). By the late 1960s, no occupied Bald Eagle territories were identified for APG.

Following the first rediscovered breeding of Bald Eagles on APG in 1977, the Directorate of Safety, Health and Environment contacted the United States Fish and Wildlife Service to initiate consultation under the Endangered Species Act, Section 7(c)(1). This consultation resulted in studies that lead to the first Bald Eagle management plan in 1986 and subsequent revisions in 1995 and 2009 (Paul 2009). These plans established the need and framework for annual monitoring of the breeding population. Here we provide the results of survey efforts (1991-2011) and discuss changes in the population relative to the breeding population within the tidal reach of the Chesapeake Bay.

STUDY AREA

APG is a 350-km² United States Department of Defense military installation located along the northwestern shore of the upper Chesapeake Bay, in southern Harford and eastern Baltimore Counties, Maryland (Figure 1). Since APG's establishment in 1917, the Aberdeen Area has been the site of intensive research and development; large-scale testing of munitions, weapons, and materiel; and a training school for ordnance officers and enlisted specialists. Due to the nature of its mission, APG is primarily forested and has extensive undeveloped shorelines. The property is embedded within the Upper Chesapeake Bay Bald Eagle Concentration Area, one of several areas within the Chesapeake Bay where Bald Eagles from along the Atlantic Coast converge (Watts et al. 2007). Throughout the Bay such concentration areas have formed within low salinity, tidal-fresh waters where prey availability is high (Watts et al. 2006). For the resident breeding population, brood provisioning and chick growth tend to be high in these areas (Markham and Watts 2008) leading to high breeding densities, high breeding success, and high productivity (Watts et al. 2006).

METHODS

Aerial helicopter surveys have been used to survey the entire study area for breeding eagles (1991-2011). Typically four to six surveys have been conducted between mid-January and late May to document nests, breeding activity, and productivity. Detected nests were plotted on topographic maps and given unique codes as names. Each nest was examined to determine its condition and status. Notes from field observations were interpreted by the authors to determine activity status according to national standards. We considered a breeding territory to be occupied if a pair of birds were observed in association with the nest and there was evidence of recent nest maintenance (e.g., well-formed cup, fresh lining, structural maintenance). We considered nests to be active if we observed a bird in an incubating posture or if we detected eggs or young in the nest (Postupalsky 1974). The number of eaglets was recorded for each nest. Due to the number of flights, we have confidence that nesting activity was well documented.

We defined breeding success as the percentage of occupied nests that contained ≥ 1 young, reproductive rate as the number of young per occupied nest, and average brood size as the number of young per successful nest. We expressed population growth rate using the

(continued)

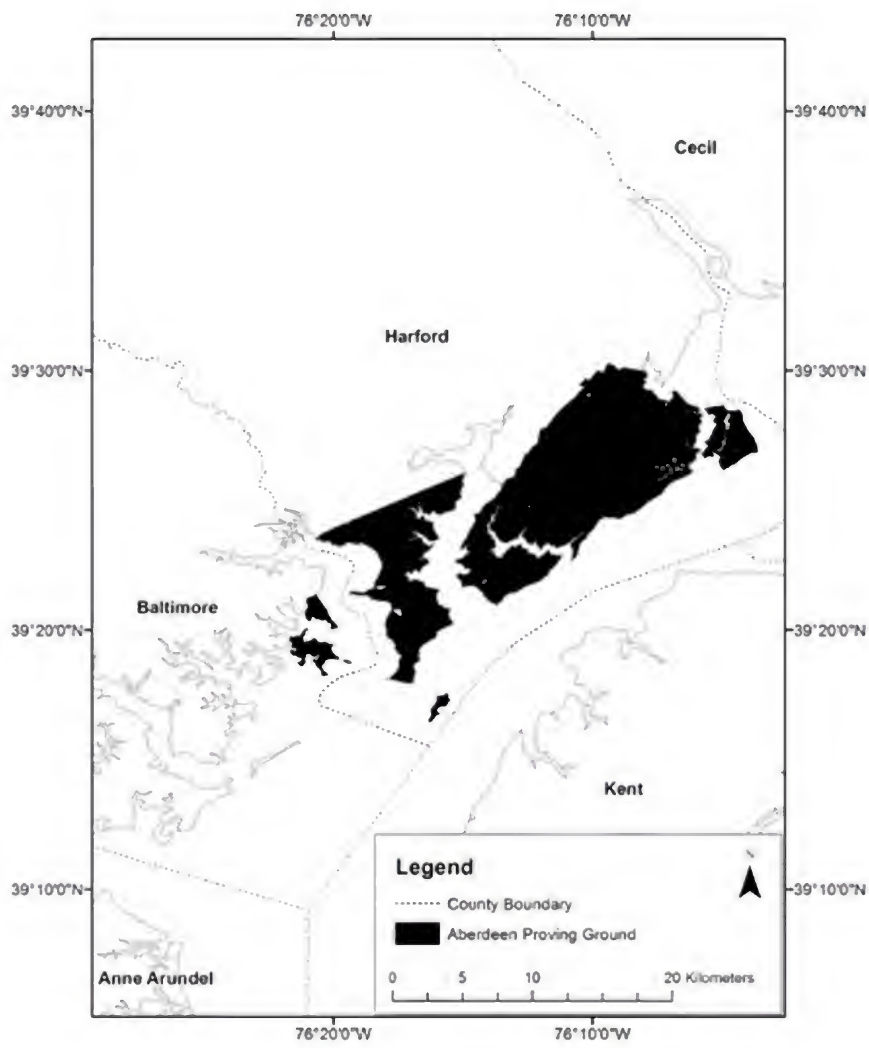

Figure 1. Aberdeen Proving Ground, Baltimore and Harford Counties, Maryland.

average time (in years) required for the population to double in size (t_{double}), the intrinsic rate of increase (r), and the average annual percent increase over the study period. We calculated average doubling time using the growth equation $N_t = N_0 e^{rt}$, where N_t is the population size in 2011, N_0 is the population size in 1977, e is the base of the natural logarithm, r is the intrinsic rate of increase, and t is the time interval between population estimates. With this configuration, $t_{\text{double}} = \ln(2)/r$. We calculated average annual percent increase as $(N_{t+1} - N_t)/N_t \times 100$.

RESULTS

Between 1977 and 2011, the Bald Eagle breeding population on APG increased from 1 pair to 58 pairs. During this period, the population grew exponentially with an average doubling time of 5.8 years. Intrinsic rate of increase (r) was 0.119. Average annual increase was $13.1 \pm 4.23\%$ (mean \pm S.E.). The annual population increase, as expressed by a percentage, was highly variable over the study period and ranged from a low of -20.6% (2005-2006) to a high of 57.9% (1998-1999). There is no indication over the survey period that this rate has shown any directional change ($R^2 = 0.042$, $F[1,17] = 0.75$, $p = 0.395$).

During the study period, we documented 464 breeding attempts (i.e., active nests) that produced 646 young (Table 1). Average annualized rates were $79.8 \pm 3.48\%$, $1.39 \pm 0.06\%$, and $1.6 \pm 0.05\%$ for breeding success, reproductive rate, and brood size, respectively. The population has exhibited tremendous forward momentum such that more than 50% of young produced over the 21-year period have been produced in the 6 years since 2005.

Survey information between 1991 and 2011 indicates that the breeding population on APG has exceeded the goal of 1.1 chicks/breeding attempt set by the Chesapeake Bay Bald Eagle Recovery Plan (Byrd et al. 1990) every year except 1997 and 1998 (Table 1). During 1997 and 1998, recorded reproductive rate was higher than that suggested for maintenance but lower than the recovery goal. For the 11-year period 1991-2001, reproductive rates for APG were virtually identical to those recorded for the broader Chesapeake Bay. The average number of chicks per active nest was 1.4 ± 0.05 (mean \pm S.E.) and 1.4 ± 0.09 for the Chesapeake Bay and APG respectively. The average number of chicks per successful nest (average brood size) was 1.8 ± 0.03 and 1.6 ± 0.05 for the Chesapeake Bay and APG respectively. These rates are not statistically distinguishable (for both comparisons, $df = 19$, F -statistic < 3.2 , $P > 0.05$).

DISCUSSION

The recovery of the Bald Eagle breeding population on APG has been dramatic. Population growth rate has been faster (doubling time of 5.8 vs 8.2 years) than that documented for the tidal reach of the larger Chesapeake Bay (Watts et al. 2008). The rate is comparable to other low-salinity reaches of the Bay that represent some of the fastest growing regions throughout the species range (Watts et al. 2006). With the exception of locations that have been developed, virtually all of the breeding territories documented during the 1930s, 1940s and 1950s have now been re-occupied. No specific estimates of the APG Bald Eagle population are available prior to the onset of the DDT era. However, given the tremendous forward momentum currently exhibited by the breeding population, it seems likely that Bald Eagles will reach nesting carrying capacity within the installation in a relatively short period of time.

TABLE 1. BALD EAGLE POPULATION SIZE AND PRODUCTIVITY WITHIN ABERDEEN PROVING GROUND, MARYLAND (1991-2011).

(Note: The 1998 survey was incomplete. Occupied Nest = pair of birds and evidence of recent nest maintenance; Active Nest = eggs or young in the nest; Successful Nest = number of nests that produced at least one young; Successful Nest/Occupied Nest = breeding success; Young/Occupied Nest = reproductive rate; Young/Successful Nest = average brood size.)

Year	Occupied Nests	Active Nests	Successful Nests	Young	Successful /Occupied ^a	Successful /Active ^a	Young /Occupied ^a	Young /Active ^a	Young /Successful ^a

A reproductive rate of 0.7 chicks/breeding attempt has been suggested to represent the threshold for population maintenance for Bald Eagles (Sprunt et al. 1973). Buehler et al. (1991a) estimated that 1.0 chicks/successful nest (equivalent to brood size) was required for sustaining breeding populations in the Bay. A reproductive rate of 1.1 chicks/breeding attempt was set as the recovery goal for the Chesapeake Bay population (Byrd et al. 1990). With the exception of 1997 and 1998, the APG population has met or exceeded the productivity target outlined in the recovery plan in every year that a survey has been conducted. The broader Chesapeake Bay reached this threshold in 1985 and has exceeded the target in all subsequent years (Watts et al. 2008). The reproductive rate documented by Tyrrell in 1936 was nearly 1.5 chicks/breeding attempt. The APG population has approached or achieved this rate in the years after 2005.

APG plays an increasingly important role in the recovery and maintenance of the Chesapeake Bay Bald Eagle population. The availability of mature trees suitable for nesting within 1 km of water has become the dominant limiting factor for Bald Eagles in the region. Human activity is the best predictor of eagle distribution within the tidal portion of the Bay. Indicators of human activity such as housing and road density, shoreline use, and boating activity have been related to nest distribution (Watts et al. 1994), shoreline use (Buehler et al. 1991b, Watts and Whalen 1997), and the likelihood of nest abandonment (Therres et al. 1993) or recolonization (B. D. Watts, Center for Conservation Biology, unpublished data). Since Bald Eagles began their most dramatic decline in the 1950s, the human population within the tidal reach of the Bay has increased by more than 50% (United States Department of Commerce 2010). A preliminary review of development occurring around eagle nests in the lower Chesapeake Bay shows that development had occurred in 55% of shoreline areas by the late 1980s (Byrd et al. 1990). Extensive undeveloped shorelines and associated uplands on APG have allowed the property to become a significant stronghold for the breeding population.

APG will continue to serve as an important Bald Eagle breeding location for the foreseeable future. APG has been actively working to restore the Bald Eagle population within the installation since the early 1980s. The Army has adopted environmental stewardship as one of its missions and it is clear that without federal ownership of this land and the demand for the ongoing mission, the upper Bay would support considerably less habitat for breeding eagles. The current Bald Eagle management plan (Paul 2009) provides broad directives to protect significant eagle habitat and outlines specific measures to reduce disturbance within known nesting, foraging, and roosting sites. Management efforts continue that are designed to mesh the needs of eagles with other military missions.

ACKNOWLEDGMENTS

The United States Army has supported breeding population surveys since the 1980s. We thank the long list of observers who have participated in surveys including Craig A. Koppie, Joseph P. Ondek, Samuel T. Voss, and Jessica Baylor. We also thank the many individuals who have managed the survey data over time including Amy Deel and Lynda Hartzell. Glenn D. Therres and Craig A. Koppie have contributed to shaping the survey.

2013 MARYLAND MAY COUNT

MICHAEL J. WELCH

*8619 Burnt Hickory Circle, Frederick, Maryland 21704-8100
manddwelch@comcast.net*

The annual May Count was held on Saturday, 11 May 2013. Results were submitted from 14 of Maryland's 23 counties, continuing a declining trend in participation over the last decade. Ten years earlier, 22 counties reported results.

Weather statewide on the count day was unsettled, with most compilers reporting significant rain in part of the day. Temperatures were generally mild, ranging from the low 60s to about 80 degrees.

A total of 304 counters in 188 parties turned up 231 species and 95,893 individual birds. Among the most unusual sightings were: a Red-throated Loon in the Monocacy River in Frederick; a Sandhill Crane at the Mt. Nebo Wildlife Management Area in Garrett; a Glaucous Gull at Hooper's Island in Dorchester; and a Common Redpoll at a feeder in Garrett. Late stragglers included 5 Black Scoters in St. Mary's, a Common Goldeneye in Talbot, a Horned Grebe in Prince George's, and a Northern Gannet in Somerset.

A comparison of this data set with that of 2003 is in accord with known trends for many species. Overall, the number of individuals was 63% of the 2003 total. The number of counties participating was 64% of 2003 counties, while the effort in terms of miles covered was 70% of 2003 values.

The absolute numbers in 2013 were up substantially over those for 2003 for a number of species and they are listed accordingly. Group A are species with known long term population growth. Group B are species that were unusually abundant in the state in the winter and spring of 2013. Group C are species for which this compiler cannot give a reason for the increase, which may not be indicative of long-term trends. The percentage increase from 2003 to 2013 is shown in parenthesis.

Group A: Wild Turkey (157%); Black Vulture (56%); Bald Eagle (98%); Red-shouldered Hawk (41%); Carolina Wren (107%)

Group B: Red-breasted Nuthatch (340%); Pine Siskin (805%)

Group C: Ruddy Duck (546%); Glossy Ibis (443%); Black-bellied Plover (844%); Semipalmated Sandpiper (119%)

A number of other species had higher counts in 2013, but the numbers were too small to characterize.

The count totals were substantially lower in 2013 as compared with 2003 for many species, even correcting for the relative effort of the two years. Many Neotropical migrants were down, but this may be primarily a function of weather conditions. Species that had the largest percentage declines (lower than 20% of 2013 total compared to the 2003 total) include: Mute Swan (3% — no surprise here); Green-winged Teal (8%); Least Bittern (17%); Snowy Egret (17%); Short-billed Dowitcher (17%); Bonaparte's Gull (14%); Royal Tern (16%); Black-

billed Cuckoo (13%); Veery (16%); Golden-winged Warbler (5% — from 20 in 2003 to 1 in 2013); and Blackpoll Warbler (16%). Again this data set alone is too small to make definitive statements about population trends for most of these species, however, breeding bird survey data shows major declines for Black-billed Cuckoo and Golden-winged Warbler.

Species seen in 2013 but not 2003 include: Common Goldeneye; Northern Gannet; Sandhill Crane; Glaucous Gull; Winter Wren; and Common Redpoll.

Species seen in 2003 but not 2013 include: Snow Goose; Tundra Swan; American Wigeon; Northern Pintail; Canvasback; Greater Scaup; Surf Scoter; Long-tailed Duck; Ring-necked Pheasant; Red-necked Grebe; Northern Goshawk; American Golden-Plover; Upland Sandpiper; Stilt Sandpiper; White-rumped Sandpiper; Western Sandpiper; Red-necked Phalarope; Lesser Black-backed Gull; Peregrine Falcon; Olive-sided Flycatcher; Yellow-bellied Flycatcher; Alder Flycatcher; Philadelphia Vireo; Sedge Wren; and Bicknell's Thrush. All but two of these were recorded in 2003 in counties that also conducted 2013 counts. The two exceptions were Western Sandpiper and Lesser Black-backed Gull, both found in Baltimore County in 2003, but where no count was conducted in 2013.

Many thanks to all the participants and compilers. I look forward to the 2014 count (10 May 2014) and hope that more counties participate. As I tell the Frederick Bird Club, it is the best day of the year to be out counting birds!

MARYLAND CHRISTMAS COUNTS (114TH CBC)

DECEMBER 2013 THROUGH JANUARY 2014

J.B. CHURCHILL

*17607 Pompey Smash Road SW, Frostburg, Maryland 21532
jchurchi@atlanticbb.net*

The weather was quite cold on some of the Maryland Christmas Bird Counts during count 114. The average low on the 23 counts was 34.2° F and the average high was 45.8° F. The arctic freeze was more of a phenomenon in January and the three counts held during that time (Annapolis-Gibson Island, Bowie, and Catoctin Mountain) had an average low of 23.7° F and high of 36.0° F. The coldest of all the counts in Maryland was Catoctin Mountain with a low temperature of 12° F and the warmest was Point Lookout with a high temperature of 68° F. The snow depth was at least 2 inches during three Maryland counts: Oakland (maximum 7.5 inches), Allegany (maximum 4 inches), and Catoctin Mountain (maximum 6 inches) with the Annapolis-Gibson Island areas having 3 inches in some places but no snow in other places. Minimum depth was 0-2 inches and maximum depth was 0-7.5 inches.

There were a number of high counts for **Double-crested Cormorants** (six different CBCs in MD had all-time highs). Four counts had high counts for **Gadwall**. Six areas had highs for **Wild Turkey**. Four areas had high counts for **Bald Eagles**, four had highs for **Turkey Vultures** and one for **Black Vultures** (among other count highs). **Northern Bobwhite** continue on their decline and were only found at two counts, both on the Eastern Shore. **Golden Eagles** were found at three counts on the Eastern Shore and one on the Western Shore. **Palm Warblers** were found at several counts, as were **Barn Owls**. Single **Ruffed Grouse**, **Yellow-breasted Chat**, **Clay-colored Sparrow**, and **Lincoln's Sparrow** observations were recorded at Oakland, Annapolis-Gibson Island, Ocean City, and Denton counts, respectively.

Observations of several species are worth highlighting including **Trumpeter Swan**, **Barrow's Goldeneye**, **Western Grebe**, **Snowy Owl**, **Ruby-throated Hummingbird**, **Western Kingbird**, **Painted Bunting**, **Dickcissel**, and **Yellow-headed Blackbird**.

The **Trumpeter Swan** was seen by Dr. Michael Braun and Terri Rafiq and soon after by Lynn Davidson who photographed it and documented it for the MD/DC Bird Records Committee.

The **Barrow's Goldeneye** was seen and photographed on the Point Lookout Count by Terry Jordan and Tyler Bell at the Elms Environmental Education Center.

Only two **Red-necked Grebes** were found (both on the Jug Bay count) whereas many would show up later in the winter season. These were found by the same observers (Gene Scarpulla and Marcia Watson) to find the count's first **Western Grebe**. The grebe was well described in a report to the MD/DC Records Committee. (Editor's note: The Records Committee accepted this report in the Western/Clark's Grebe complex, *Aechmophorus* genus.)

There was a lot of interest in this year's invasion of **Snowy Owls** and we had two (one at the Ocean City count and the other at Chesterville) counted on MD Christmas Counts.

Compared to annual or almost annual occurrences of **Rufous Hummingbirds**, the wintering **Ruby-throated Hummingbird** found on the Annapolis-Gibson Island count was very unusual.

A **Western Kingbird** was found on the Ocean City count and they also had their first **Western Tanager**.

A **Painted Bunting** was seen by Thomas Ostrowski, then later by Jeff Shenot, and relocated on count day by Taylor Mclean for the Jug Bay count at the Merkle Wildlife Sanctuary.

A **Dickcissel** that had been making use of the bird feeders at Sean McCandless' house made an appearance on count day for Elkton.

Some other interesting birds included two **Osprey** on the Annapolis-Gibson Island Count and **Spotted Sandpiper** on the Annapolis-Gibson Island and Jug Bay counts. **Rufous Hummingbirds** were on each of those counts as well. There was a **Sandhill Crane** on the Jug Bay Count (count week), one on the Lower Kent County Count, and two each on both the Seneca and Bowie Counts.

TABLE LEGEND

Bolded species name = unusual for the count

Bolded data value = high count record

cw = observed during Count Week
